

What capabilities does a Pallet lift have?

The pallet lift is equipment with the capability to handle and maneuver pallets of different weights and size. This lift can function as standalone equipment on its own strength; and at the same time it is amenable to function with other types of heavy equipment such as cranes, forklifts and the like, as an attachment.

The design of a pallet lift typically comprises a pair of forks that are placed beneath the pallet to be lifted, with a bar that stabilizes the pallet when it is in the air. The forks are mounted to a hydraulic system. In a variant to this design, the lift itself is kept fixed, while an overhead lift or tractor performs the movement of the pallets.
